## Diagnosing bias and variance

How do you tell if your algorithm has a bias or variance problem?

If the model's cross validation error  $J_{cn}$  is much higher than the training error  $J_{train}$ , this is an indication that the model has...

- high variance
- O Low bias
- Low variance
- O high bias
- **⊘** Correct

When  $J_{cv}>>J_{train}$  (whether  $J_{train}$  is also high or not, this is a sign that the model is overfitting to the training data and performing much worse on new examples.

## Bias/variance examples

↑ Baseline performance : 10.6% 10.2% 10.6% 14.4% 10.6% : 10.8% 15.0% O.5% 15.5% O.5% Training error  $(J_{train})$ Cross validation error  $(J_{cv})$ : 14.8%  $\downarrow^{4.0\%}$ high high high bias bias high variance variance

Which of these is the best way to determine whether your model has high bias (has underfit the training data)?

- O See if the training error is high (above 15% or so)
- Compare the training error to the baseline level of performance
- Ompare the training error to the cross validation error.
- O See if the cross validation error is high compared to the baseline level of performance

Correct. If comparing your model's training error to a baseline level of performance (such as human level performance, or performance of other well-established models), if your model's training error is muchhigher, then this is a sign that the model has high bias (has underfit).

## Debugging a learning algorithm

You've implemented regularized linear regression on housing prices

$$J(\vec{\mathbf{w}}, b) = \frac{1}{2m} \sum_{i=1}^{m} (f_{\vec{\mathbf{w}}, b}(\vec{\mathbf{x}}^{(i)}) - y^{(i)})^{2} + \frac{2}{2m} \sum_{j=1}^{n} w_{j}^{2}$$

But it makes unacceptably large errors in predictions. What do you try next?

- → Get more training examples
- → Try smaller sets of features x, x², x', x', x', x'
   → Try getting additional features ← Try adding polynomial features  $(x_1^2, x_2^2, x_1x_2, etc)$

fixes <u>high variance</u> fixes high variance fixes high bias fixes high bias

 $\rightarrow$  Try decreasing  $\lambda \leftarrow$ 

fixes high bias

You find that your algorithm has high bias. Which of these seem like good options for improving the algorithm's performance? Hint: two of these are correct.
☐ Collect more training examples
$lacksquare$ Decrease the regularization parameter $\lambda$ (lambda)
Orrect Correct. Decreasing regularization can help the model better fit the training data.
Remove examples from the training set
✓ Collect additional features or add polynomial features
<ul> <li>Correct         Correct. More features could potentially help the model better fit the training examples.   </li> </ul>
You find that your algorithm has a training error of 2%, and a cross validation error of 20% (much higher than the training error). Based on the conclusion you would draw about whether the algorithm has a high bias or high variance problem, which of these seem like good options for improving the algorithm's performance? Hint: two of these are correct.
$arnothing$ Increase the regularization parameter $\lambda$
Correct Yes, the model appears to have high variance (overfit), and increasing regularization would help reduce high variance.

○ Correct Yes, the model appears to have high variance (overfit), and collecting more training examples would help reduce high variance.
